2. Executive Summary

This report covers the work carried out by The Food and Environment Research Agency (Fera), formerly known as the Central Science Laboratory (CSL), within project FS231058 '*Trichinella* in UK Wildlife', commissioned by the UK Food Standards Agency over the period of 1st April 2009 to 31st March 2012. A subsequent extension to the project ending on the 31st May 2013 is detailed as an appendix to this report and all objectives and methods for this further work are as reported here.

The work was commissioned in support of the UK application to the European Member States (MSs) to be officially recognised as a region presenting a negligible risk of *Trichinella* to domestic swine, as per Commission Regulation (EC) No 2075/2005¹ of 5 December 2005 and laying down specific rules on official controls for *Trichinella* in meat. This work produced wildlife data, required as supporting evidence for the above-mentioned application and mandatory for upholding the status, once awarded.

Within the period covered by this project report (01/04/2009 – 31/03/2012) 1503 foxes from Great Britain (GB) and 492 from Northern Ireland (NI) were tested for *Trichinella*. All foxes from both GB and NI tested negative.

Over the same period an investigation of alternative wildlife species was undertaken and 31 cetaceans and 11 pinnipeds were tested and found to be negative for *Trichinella*. Most animals had been found on the Cornish coast and were investigated as part of the UK Cetacean Strandings Investigation Programme (www.ukstrandings.org).

3. Introduction and Background

Trichinellosis is a zoonotic disease, caused in humans by the ingestion of raw or undercooked meat containing larvae of the nematode genus, *Trichinella*. Species of *Trichinella* can be found worldwide in a variety of hosts, ranging from mammals to birds and reptiles. The main sources of human infection in Europe are meat from domestic pigs, wild boar and horses, though occasionally more exotic types of meat are involved. Symptoms of trichinellosis are usually only reported in humans as infected animals do not generally display clinical signs. The classical symptoms of trichinellosis in humans are gastrointestinal signs (diarrhoea, nausea, vomiting), fever, myalgia and periorbital oedema. Myocarditis, encephalitis and thromboembolic diseases are complications more likely, but not exclusively, expected to occur in severe cases and are the main cause of fatalities. Trichinellosis is rarely, however, associated with fatalities (worldwide mortality is reported to be <0.2%) but a recent outbreak in Spain (ProMED, 6 March 2011, Archive number 20110306.0735),

¹ OJ L 338, 22.12.2005, p. 60–82 (ES, CS, DA, DE, ET, EL, EN, FR, IT, LV, LT, HU, NL, PL, PT, SK, SL, FI, SV)
OJ L 306M, 15.11.2008, p. 452–474 (MT)

involving one fatality, is a reminder of the importance of ongoing testing, especially of high risk products in endemic areas.

Routine testing (as specified in Commission Regulation (EC) 2075/2005) is mandatory within European Union Member States (EU MSs) to prevent infected meat from pigs and other relevant species entering the human food chain. Trichinellosis (and agents thereof) in animals and foodstuffs is notifiable to the EU in the framework of Directive 2003/99/EC ('Zoonoses Directive').

Since 2005, data reported under this framework are analysed and published annually in the EU Summary Report on Trends and Sources of Zoonoses and Zoonotic Agents and Food-borne Outbreaks by the European Food Safety Authority (EFSA). These data also include information on human outbreaks.

Within this system and due to the combined effort of expert networks such as the network of respective National Reference Laboratories (NRLs), or the International Commission on Trichinellosis, the testing and the reporting of *Trichinella* have continually improved over the years. As a consequence, the epidemiological situation in the EU MSs is much better understood and has enabled a move towards risk-based surveillance if certain conditions are met.

One example of such risk-based surveillance is the official recognition of *Trichinella*-free production, and the sanctioning of risk based monitoring programmes for *Trichinella* in pigs, which was introduced into EU legislation in 2006. These changes to legislation also provided a framework for regions to be recognised as presenting a negligible risk of *Trichinella* in domestic pigs to allow exemption from *Trichinella* testing of domestic pigs kept solely for fattening and slaughter. To qualify for negligible risk status certain requirements must be fulfilled, in accordance with Commission Regulation (EC) 2075/2005 before the application can be brought forward to the EU MSs for approval. These requirements include submission of evidential data from wildlife as well as livestock. The obligation is to demonstrate that a wildlife monitoring programme has been put in place using the most suitable indicator wildlife species and detection technique, in order to verify that the animals are effectively 'free' from *Trichinella*. It is within this context that the work described here has been carried out.

Trichinella larvae have been described in over 150 species of mammals worldwide, as well as birds and reptiles (Pozio, 2005). The sylvatic cycles are determined by the potential host species available (FAO/WHO/OIE, 2007). In spite of the broad host spectrum of *Trichinella* spp., the greatest biomass of these parasites occurs amongst the Carnivora and the artiodactylid family Suidae (Pozio and Murrell, 2006). Carnivorous and omnivorous animals (mainly those with cannibalistic and scavenging behaviour) holding a high position in the food chain are generally regarded as suitable indicator animals (Anon, 1996). In most parts of Europe, the red fox is generally

considered the indicator of choice, though over the past years the importance of the racoon-dog as a natural reservoir for *Trichinella* infection has increased notably, especially in northern regions (Kapel *et al.*, 2001; Oivanen, 2005). Literature review and consideration of ecological as well as practical factors concluded that the red fox is the most suitable indicator wildlife species for *Trichinella* in the United Kingdom.

Species other than foxes (such as marine mammals) were given consideration in the context of potential introductory routes after a report from the Scientific Panel on Biological Hazards on the "Request for an opinion on the feasibility of establishing *Trichinella*-free areas, and if feasible, on the increase in risk to public health of not examining pigs from those areas for *Trichinella* spp." (EFSA, 2005) concluded that natural boundaries (e.g. water) do not form barriers that can effectively prevent introduction or establishment of *Trichinella* in reservoir animals in a special habitat.

Collection of data on *Trichinella* in Great Britain (GB) wildlife, commissioned by the FSA, commenced in 1999. Between November 1999 and March 2006, 3000 foxes from throughout GB were tested for *Trichinella*. All 3000 foxes tested negative for *Trichinella*. Validation data demonstrated a test sensitivity of >0.9 for a single infected fox (10g sample per animal and an assumed infection level of 1 larva per gram) and therefore the study demonstrated an upper 95 percentile confidence limit of 0.1% prevalence in foxes in GB. Continued surveillance was then necessary to demonstrate that the prevalence had not increased. Based on an assumed GB fox population size of 240,000 (Webbon *et al.*, 2004) with no spatial stratification and an assumed initial incidence of 2 or 10 infected animals, the sample size for continued surveillance was calculated. Cumulative probabilities for detection following annual surveys with varying numbers of foxes were calculated and minimum (n=10 foxes) and maximum (n=2 foxes) predicted times to detection were estimated. The calculations suggested that annual testing of 450 foxes would ensure detection of disease under these assumed conditions in the range of 7-11 years and this number was selected to satisfy considerations of sensitivity, practicality and cost.

Therefore, from November 2006 onwards, the overall objective of this study has been to provide a rolling programme of carcass collection and diagnosis sufficient for maintaining disease awareness, i.e. the testing of 450 foxes per annum from GB. Other species (cetaceans and pinnipeds) were tested as and when samples became available through the UK Cetacean Strandings Investigation Programme, which is jointly funded by Defra, the Welsh Assembly Government and the Scottish Government (www.ukstrandings.org).

In January 2007, the disease awareness programme was expanded to include the testing of 150 foxes per annum from Northern Ireland (NI). This is conducted in collaboration with the Department of Agriculture and Rural Development Northern Ireland (DARDNI) and the Agri-Food and Biosciences Institute Northern Ireland

(AFBINI). The lower sample numbers collected are indicative of higher *Trichinella* prevalence rates and the practicality of sampling a smaller fox population in NI.

The last reported finding of *Trichinella* in livestock in the UK dates back to 1979 and came from NI (information held by the Animal Health and Veterinary Laboratories Agency (AHVLA, formerly VLA)). No human cases acquired from meat produced in the UK have been reported since 1953, when an outbreak occurred in Liverpool, following the consumption of meat from an infected domestic pig (Semple *et al.*, 1954). However, ten cases of trichinellosis were diagnosed in the UK between 2000 and 2012. This included an outbreak involving eight cases and was caused by the consumption of pork salami imported from northern Serbia (Milne *et al.*, 2001). The remaining two cases were travel related: one in England and Wales in 2001, and the other in Scotland in 2010 in a person who had eaten partially cooked meat in France. There were no human cases in 2012 in the UK.

The last report of *Trichinella* in wildlife in Great Britain was from a fox sampled in Truro, Cornwall, in 1957 (Oldham & Beresford-Jones, 1957). Whereas Great Britain continues to produce negative findings in wildlife, trichinellosis is found at low levels in Northern Ireland where in both 2007 and 2009, one positive fox has been detected respectively (Zimmer *et al.*, 2009 and Final Report to the FSA ‘Survey of *Trichinella*’ Project Code M01042, covering the period of 01/11/2005 - 31/03/2009).

Between 2002 and 2009 the number of confirmed human cases of trichinellosis reported in EU MSs increased continuously from under 50 in 2002 to 748 in 2009 (EFSA: EU summary reports on trends and sources of zoonoses, zoonotic agents and food-borne outbreaks; electronic versions are available on the EFSA website). This may not have necessarily been a true reflection of an increasing trend but partly due to improved monitoring and reporting as well as to the accession of new EU MSs in 2004 and 2007, which since had accounted for over 80 % of the annual cases in the EU. Another point made in the 2009 EFSA report was that the number of reported confirmed cases (748 in 2009) was markedly lower than the total number of reported cases (1073 in 2009). This could have been due to practical procedures during outbreaks, where only a limited number of clinical cases may be laboratory confirmed, the others may be treated/reported based on clinical symptoms and the epidemiological link. In 2010 trichinellosis caused 223 confirmed human cases in the European Union. Compared with the previous years, the number of human trichinellosis cases at the European Union level declined remarkably. Also, in 2010 fewer *Trichinella* positive pigs were reported than in the previous year. The parasite was more prevalent in wildlife (EU summary report on zoonoses, zoonotic agents and food borne outbreaks 2010). In 2011 trichinellosis caused 268 confirmed human cases in the European Union. Although the number of cases was slightly higher in 2011 compared with 2010, human trichinellosis cases remained at a low level in the European Union compared with the number of reported cases in 2009 and previous years. In 2011, *Trichinella* was found slightly more often in pigs than it was in 2010. The parasite was more prevalent in wildlife than in farmed animals (EU summary report on zoonoses, zoonotic agents and food borne outbreaks 2011).

Within the EU, the main source of human trichinellosis continues to be pork and wild boar meat. In EU MSs most of the biomass of *Trichinella* parasites is circulating among wildlife (carnivores and wild boars) and human infections often follow the consumption of untested game meat consumed by hunters and their relatives and friends.

4. Project Objectives, Milestones & Deliverables

Objective 1: To provide an annual programme of wildlife carcass collection and *Trichinella* testing sufficient for maintaining disease awareness (assumed at this stage to be approximately, per annum, 450 foxes from GB and 150 foxes from Northern Ireland) as part of a rolling programme. In December of each project year (Years 1 and 2), the decision to continue with the project (in Years 2 and 3, respectively) will be made.

Objective 2: To continue to assess the value of testing other wildlife species and carry out a limited survey of alternative wildlife species where appropriate and where agreed with the FSA.

Objective 3: To participate in the UK Quality Assurance (QA) testing programme and assess the value of serological *Trichinella* testing methods for wildlife.

Objective 4: Consider the outcome of currently ongoing EFSA project in regard to the sampling and monitoring of *Trichinella* and provide feedback to the FSA.

Milestone	Target date	Title
01/01	31/03/2010	Complete collection and diagnostic testing of a minimum of 450 GB foxes and 150 NI foxes to provide data to satisfy disease awareness
02/01	31/03/2010	Review, as required, the testing of alternative wildlife species including, where necessary, limited sampling and laboratory diagnoses. Update recommendations on use of alternative species as required.
03/01	31/03/2010	Participate in NRL QA programme (with appropriate dates).
04/01	31/03/2010	Consider outcome of recent EFSA project and its implications for <i>Trichinella</i> surveillance. Update / consult FSA and implement any changes as agreed.
01/02	31/03/2011	Complete collection and diagnostic testing of a minimum of 450 GB foxes and 150 NI foxes to provide data to satisfy disease awareness as set out for the period covered by the first year.
02/02	31/03/2011	Review, as required, the testing of alternative wildlife species including, where necessary, limited sampling and laboratory diagnoses. Update recommendations on use of alternative species as required.
03/02	31/03/2011	Participate in NRL QA programme (with appropriate dates).
01/03	31/03/2012	Complete collection and diagnostic testing of a minimum of 450 GB foxes and 150 NI foxes to provide data to satisfy disease awareness as set out for the period covered by the first year.
02/02	31/03/2012	Review, as required, the testing of alternative wildlife species including, where necessary, limited sampling and laboratory diagnoses. Update recommendations on use of alternative species as required.
03/03	31/03/2012	Participate in NRL QA programme (with appropriate dates).

Deliverable	Target date	Title
		Monthly reports of test results (submitted on spreadsheet), including details of the animals tested, will be sent to the FSA during the project.
01/01	31/03/2010	Submission of report to cover all work carried out in contract period and previous surveys as appropriate.
02/01	31/03/2011	Submission of report to cover all work carried out in contract period and previous surveys as appropriate.
03/01	31/03/2012	Submission of draft final report to cover all work carried out in contract period and previous surveys as appropriate.

5. Experimental Procedures

5.1. Overview

Foxes were collected using a network of gamekeepers, shooters, landowners and staff from Fera and DARDNI. The fox carcasses were submitted to one of two Fera sites (Woodchester Park, Gloucestershire or York), or to AFBINI, where relevant muscles were removed and the age, sex, weight and overall condition (at time of death) of the individual animals was recorded. Fox body condition was assessed to be good, fair or poor with notes (e.g. underweight, hair loss, injuries etc) taken for animals in less than good condition. Each fox record also included a unique ID number, the map coordinates of its original location and the collection or kill date.

All *Trichinella* diagnostics were carried out at Fera York, using a magnetic stirrer method for pooled sample digestion based on Commission Regulation (EC) 2075/2005. This is the standard test for meat including domestic pigs and wild boar, albeit slightly modified for fox muscle (Zimmer *et al.*, 2008).

If any suspect positives had been found, they would have been confirmed by Keith Hunt at the Animal Health Veterinary Laboratories Agency (AHVLA), the UK National Reference Laboratory (NRL) for trichinellosis, and speciation would then have been carried out, using recognised PCR methods, by Dr E. Pozio, Istituto Superiore di Sanità, Rome, Italy, currently acting as the Community Reference Laboratory for Parasites (CRL).

5.2. Sampling of Foxes

Most fox carcasses were obtained from gamekeepers and landowners during normal pest control duties, but in some instances by direct culling by staff employed on this study. Carcass collection had, as far as possible, been based on known, or estimated, fox population densities. Greatest numbers are to be found in lowland areas, and sampling aimed predominantly for one fox per 10 km square, but allowed for multiple foxes in areas of higher density. From the point of collection carcasses were identified

by a combination of the map co-ordinate (of the collection point), or, where known, the kill location, the collection date and a 'fox number' (needed in cases where several carcasses were collected from the same location at the same time). Upon receipt of the carcass details at Fera, York, data was logged onto a Microsoft Access database and assigned a new unique identifier called 'Access Number'. All collected carcasses were then kept chilled at approximately + 4°C (never frozen) until post mortem examination.

Foxes across NI were collected or culled by DARDNI and then delivered to AFBINI for post mortem. For foxes sampled across GB, post mortems were carried out at Fera, York. All tissue samples (GB and NI) were diagnosed at Fera York.

5.3. Sampling of Cetaceans and Pinniped

Cetaceans and pinnipeds continued to be tested as and when samples became available through the UK Cetacean Strandings Investigation Programme, which is jointly funded by Defra, the Welsh Assembly Government and the Scottish Government (www.ukstrandings.org).

All cetacean and pinniped samples tested within this project were kindly provided by colleagues from the Animal Health Veterinary Laboratories Agency (AHVLA). With the exception of a Hooded Seal, which had been rescued in Morocco and then kept in the Gweek Seal Sanctuary, the majority of samples originated from animals stranded on the coast of Cornwall.

5.4 Post Mortem Procedure

The post mortem and diagnostic procedures employed are outlined below but have been described more fully in the 'Project Report (Part M01042): Trichinellosis in Wild Foxes in Great Britain, 1999-2006 Surveys' (previously submitted to FSA) and have been published (Zimmer *et al.*, 2008).

Studies on the predilection sites of *Trichinella* spp. in foxes (*Vulpes vulpes*, *Alopex lagopus*, *Vulpes vulpes fulva*), using experimentally infected animals, have been published (Kapel *et al.*, 1994, 2005; Nöckler and Voigt, 1997). The overall results were comparable with findings from a study on predilection sites in naturally infected arctic foxes (Kapel *et al.*, 1995), and established the orbital muscles, leg muscles and tongue as predilection sites for encapsulated *Trichinella* species. Based on these findings, as well as practical aspects, lower foreleg extensor (*m. extensor carpi radialis*), upper foreleg biceps (*m. biceps brachii*), masseter and tongue muscles were collected from all carcasses where possible. During post mortem the age of the foxes was determined visually using dental characteristics as described in Giraudoux *et al.* (2001). Details were also noted on the animal's condition, weight, age and sex.

5.5. Diagnostic Method for Foxes

Various laboratory methods have been officially approved for the detection of *Trichinella* in fresh meat. The magnetic stirrer method for pooled-sample digestion (artificial digestion method) was considered a reliable method for routine use. Annex I, Chapter I, of Commission Regulation (EC) No 2075/2005 describes this method for the testing of pigs. The method requirements for the risk-based wildlife monitoring programme, as outlined in Annex IV, Chapter II, of the above regulation required the application of the ‘most suitable indicator animal and detection technique’. The method used by Fera for M01042 was that of a modified magnetic stirrer method for pooled-sample digestion (artificial digestion method), based on Annex I, Chapter I, of Commission Regulation (EC) No 2075/2005. This was developed specifically for foxes in cooperation with Keith Hunt, a member of the MedVetNet *Trichinella* work package (TrichiNet) and head of the UK National Reference Laboratory for Trichinellosis, VLA Weybridge.

Sample preparation

A minimum of 10 g of muscle from each animal was used as this provided a good compromise between muscle availability and sensitivity for the diagnostic procedures.

All muscles used for analysis were trimmed of fat and fascia, and individual samples of 10 – 10.5 grams were prepared from the foreleg extensor muscles. If the required amount of muscle was not available from the extensors, the weight was made up with biceps muscle, or on occasion, with masseter muscle, (e.g. in case of damaged or missing leg muscle). Up to 20 individual samples were combined to give a total of 200 – 210 grams of muscle tissue. The bulked tissue samples were then homogenised in a blender.

Artificial digest

The homogenised material was placed in a 5 litre beaker, and 1 litre of tap water at 44 – 47°C added. A magnetic stirring rod was added and the beaker placed onto a preheated plate of a heated magnetic stirrer in order to disperse the muscle tissue. A further 3 litres of tap water was then added and the temperature adjusted to 44 – 47°C. Eighty millilitres of 18.5% Hydrochloric acid (HCl) was added, resulting in a 0.12 N HCl final solution. The solution was stirred well and 40 g ± 0.5 g of pepsin added (pepsin ratio: 1%, w/v). The beaker was covered with aluminium foil and stirred vigorously for 60 min. Temperature checks were carried out every 10 min. The digest time was extended if the temperature dropped below 45°C during the digest or if big lumps of meat were still visible, but did not exceed 90 minutes in total.

Larval recovery

After completion, the digest was taken off the magnetic stirrer and left to sediment for 30 minutes.

After sedimentation the top 3 litres (Sediment A) were poured slowly through two sieves (250 mm mesh over 38 mm mesh). The 250 mm sieve was then rinsed over the 38 mm sieve, and the 38 mm sieve gently but thoroughly spray washed with hand warm tap water. The material remaining in the 38 mm sieve after spray washing was collected in a bowl in less than 100 ml of water. This was then transferred to a 100 ml measuring cylinder, topped up to 100 ml with tap water and left to sediment for 10 min. After sedimentation the top 90 ml were siphoned off. The remaining suspension was stirred and checked if sufficiently clear for examination. If not, another 30 ml (or optionally 90 ml) of tap water could be added, and sedimentation repeated for 10 minutes and the subsequent top 30 (or 90) ml siphoned off. The last washing step, using/adding 30 ml of tap water, could be repeated 2 – 4 times until sufficiently clear for inspection. The final, clarified 10 ml was used for examination for the presence of *Trichinella* larvae ('trichinae'). Where the suspension was still not sufficiently clear after four washes, the 10 ml were divided into several portions for examination.

The remaining digest material from the 5 litre beaker (Sediment B) was processed exactly as described for Sediment A, using the same sieves. The final recovery from the 38 mm sieve was carried out with increased water pressure to minimise any chance of trichinae remaining on the sieve.

Microscopy, Reporting of Results and Positive Findings

Examination of the recovered washings was carried out immediately after the digest procedures were completed using a stereo-microscope with adjustable sub-stage transmitted light source at x20 magnification.

If any suspect positives had been found, they would have been confirmed using recognised PCR methods by Keith Hunt at the Animal Health Veterinary Laboratories Agency (AHVLA), the UK National Reference Laboratory (NRL) for Trichinellosis with speciation by Dr E. Pozio, Istituto Superiore di Sanità, Rome, Italy, currently acting as the Community Reference Laboratory for Parasites (CRL).

5.6 Diagnostic method for Cetaceans and Pinnipeds

Diagnostics followed in principle the method used for foxes but was amended to account for the different predilection sites (masseter, tongue, diaphragm and tail or flipper muscle were used). Some of the marine samples were diagnosed individually to account for the frequency of sample arrival. Where possible, fifty grams of muscle tissue per animal were used for the digest in order to increase the sensitivity.

5.7 Quality Assurance

Fera operates under ISO 9001:2000 certification and conducts regular internal quality checks specifically designed to assess diagnostic competence. Fera also participates in national *Trichinella spiralis* quality assessments, which are coordinated by the National Reference Laboratory for Trichinellosis at AHVLA Weybridge and are mandatory for all laboratories carrying out *Trichinella* testing of pig meat. In the period of this report, eleven assessments were completed at Fera (see Table 6.3.1).

6. Results and Discussion

6.1. *Trichinella* in Foxes

Between 1st April 2009 and 31st March 2012 a total of 1722 foxes from GB were collected of which 1503 were tested for *Trichinella*. All foxes were found to be negative for *Trichinella*.

A monthly summary for GB fox carcasses collected and broken down for each month for the study period, 1st April 2009 – 31st March 2012, is given in Appendix 8.1. Appendix 8.2. shows a map of the collection (or kill) locations for the GB foxes tested for *Trichinella* infection under FS231058. Appendix 8.3 shows the estimated rural fox density per square kilometre as derived from Webbon & Harris (2004). Appendix 8.4 shows a map of the collection (or kill) locations for all GB foxes tested for *Trichinella* since 1999. Individual data for foxes tested under FS231058 is presented in Appendix 8.5.

Tested fox data is also summarised for gender (Appendix 8.6.), age (Appendix 8.7.), condition (Appendix 8.8.) and weight (Appendix 8.9.). Overall, and where recorded, approximately 46% of GB tested foxes were female, were predominantly young adults (19% were aged and 2% juvenile), in good condition (29% were fair and only 8% classed as in poor condition) and with the average fox weighing 5.9 kg.

Between 1st April 2009 and 31st March 2012 a total of 502 foxes from NI were collected, of which 492 were tested for *Trichinella*. All foxes were found to be negative for *Trichinella*. Collection (or kill) locations for all NI foxes collected for *Trichinella* infection under FS231058 are mapped in Appendix 8.2. with individual data for tested foxes shown in Appendix 8.10.

A monthly summary of NI fox collections broken down for each month is given in Appendix 8.1. NI tested fox data is summarised for gender (Appendix 8.11), age (Appendix 8.12), condition (Appendix 8.13) and weight (Appendix 8.14). Overall, and where recorded, approximately 45% of NI tested foxes were female, 90 % were recorded as adults, and of those further classified, 26% were aged and 74% young adults. Most foxes were submitted in good condition (20% were fair and 21% classed as in poor condition) and with the average fox weighing 5.8 kg.

When data collected under FS231058 is added to previous studies (1st October 1999 – 31st March 2009) 5927 GB foxes have been tested. No *Trichinella* positive foxes have been found in GB. When the current NI data is added to previous studies (2003/4 and January 2007 – March 2009), a total of 1013 foxes have been tested. Only two of these NI foxes have presented as positive to *Trichinella* giving a prevalence of 0.2%. No national survey data exists on fox numbers in NI so it is not possible to estimate the total number of positive animals in NI.

6.2. *Trichinella* in alternative wildlife species

Between 1st April 2009 and 31st March 2012, a total of 31 cetaceans (13 harbour porpoises, 2 striped dolphins, 15 common dolphins and 1 Cuvier's beaked whale) and 11 pinnipeds (10 grey seals, 1 hooded seal) were tested for *Trichinella*. The individual animals and further details are listed in 6.2.1 below. All samples tested negative.

6.2.1 Table to show details of cetaceans and pinnipeds tested at Fera for *Trichinella* during project FS231058

Species	Age	Sex	Location	Date of diagnostic test
Harbour porpoise	Juvenile	Male	Gyllyngvase Beach, Falmouth, Cornwall	23/04/2010
Grey seal	3 months	Male	Pendeen, Cornwall	23/04/2010
Hooded seal	4 years	Male	Originally rescued from de Laayoune, Morocco. Afterwards long term captive in Seal Sactuary Gweek, Cornwall	23/04/2010
Grey seal	6 months	Not Recorded	Rescued released pup found dead on Great Western Beach, Newquay, Cornwall	18/05/2010
Harbour porpoise	Juvenile	Female	Praa Sands, Cornwall	09/07/2010
Common dolphin	Juvenile	Male	Church Cove, Gunwalloe, Cornwall	04/11/2010
Common dolphin	Adult	Male	Lamorna Cove, Cornwall	04/11/2010
Grey seal	Juvenile	Female	Perranporth, Cornwall	04/11/2010
Harbour porpoise	Adult	Female	Sennen Cove, Cornwall	04/11/2010
Grey seal	1 year	Female	Wherrytown, Penzance, Cornwall	23/11/2010
Harbour porpoise	Juvenile	Male	Fistral Beach, Newquay, Cornwall	23/11/2010
Harbour porpoise	Adult	Female	Porthminster, St. Ives, Cornwall	23/12/2010
Common dolphin	Juvenile	Female	Marazion, Cornwall	18/01/2011
Grey seal	8 months	Male	Porthkidney, Lelant, Cornwall	18/01/2011
Grey seal	6 weeks	Male	Crantock, Newquay, Cornwall	18/01/2011
Common dolphin	Adult	Male	Porthmeor, St. Ives, Cornwall	01/02/2011
Common dolphin	Adult	Male	Looe, Cornwall	01/03/2011
Harbour porpoise	Adult	Male	Marazion, Cornwall	01/03/2011
Common dolphin	Adult	Female	Gyllyngvase Beach, Falmouth, Cornwall	01/03/2011

Species	Age	Sex	Location	Date of diagnostic test
Cuviers Beaked Whale	Juvenile	Female	Port Quin, Cornwall	08/03/2011
Grey seal	Juvenile	Male	St. Agnes, Cornwall	08/03/2011
Common dolphin	Adult	Male	Porthtowan, Cornwall	09/03/2011
Grey seal	Adult	Male	Newlyn, Cornwall	09/03/2011
Harbour porpoise	Juvenile	Female	Marazion, Cornwall	08/04/2011
Grey seal	1yr old	Female	Insufficient records but likely Nr Newcastle	10/06/2011
Striped dolphin	Juvenile	Male	Upton Towans, Gwithian, Cornwall	02/08/2011
Grey seal	Adult	Female	Porthmeor, St. Ives, Cornwall	02/08/2011
Striped dolphin	Adult	Male	Carne Beach, Roseland Peninsula, Cornwall	02/08/2011
Harbour porpoise	Juvenile	Male	Praa Sands, Cornwall	18/10/2011
Common dolphin		Male	Padstow, Cornwall	25/11/2011
Common dolphin	Juvenile	Male	Porthcothan, Cornwall	30/11/2011
Common dolphin	Juvenile	Male	Par Beach, Cornwall	02/11/2011
Common dolphin	Adult	Male	Godrevy, Cornwall	08/12/2011
Common dolphin	Calf	Female	Holywell Bay, Cornwall	08/12/2011
Common dolphin	Adult	Female	Millendreath, Cornwall	14/12/2011
Common dolphin	Adult	Male	Porthmeor, St. Ives, Cornwall	14/12/2011
Harbour porpoise	Juvenile	Male	Carne Beach, Roseland Peninsula, Cornwall	25/01/2012
Harbour porpoise	Juvenile	Female	Porthpean, St Austell, Cornwall	25/01/2012
Harbour porpoise	Juvenile	Female	Whitesand Bay, Sennan Cove, Cornwall	25/01/2012
Harbour porpoise	Juvenile	Female	Kennack Sands, Cornwall	09/02/2012
Common dolphin		Female	Widemouth Bay, Cornwall	14/03/2012
Harbour porpoise			Porthmeor, St. Ives, Cornwall	14/03/2012

6.3. Assessment of the value of testing other wildlife species

Foxes remain the preferred species for wildlife surveillance in the EU due to their position in the food chain and the domestic cycle, their widespread and relatively homogenous distribution and the practicalities of surveillance. In the UK, however, there are some other animal species that are susceptible to *Trichinella* (eg wild boar, rats, badgers, polecats, omnivorous and carnivorous birds, etc) and so it is important to consider whether these would be good indicators for the *Trichinella* prevalence in wildlife. According to Stojcevic et al. (2004) and Pozio et al. (2008) rats are not ideal indicators for *Trichinella*, as opposed to foxes, because their role as *Trichinella* reservoirs is still under discussion and they only represent a lateral branch of the domestic cycle. Furthermore, rats are not ideal hosts for all *Trichinella* species and they are unable to maintain infestation in a region. It must also be considered that although the detection of *Trichinella* in rats caught on farm or waste site may give information about the circulation of *Trichinella* among domestic pigs and/or wildlife, the absence of infested rats cannot lead to the conclusion that there is no circulation in the investigated region (Pozio, 2008). Also, the infestation source is the same for pigs and rats (remnants and offals of pigs carcasses) and it is difficult to calculate population sizes of rats that enter farms.

Licensed badger culling in the UK may increase the opportunity to sample this species in the future. However, and as reported previously, the relatively high incidence of TB in this species may require extensive (and therefore costly) containment practices for carcass handling and this cost may not justify the objective. Other wildlife species susceptible to *Trichinella* may add value to a surveillance exercise, for example testing of carnivorous birds may define a possible risk of incursion. However, for these and all other considered species, epidemiological roles are not well defined and so the cost-benefit of active surveillance does not currently justify their inclusion in the monitoring exercise.

Wild boars do not exist in large numbers throughout GB and only two small populations exist in the southwest.

Therefore, the red fox (*Vulpes vulpes*) continues to represent the best opportunity for detecting *Trichinella* in UK wildlife: The fox is widely used throughout Europe as an indicator animal and although data for UK population densities (see Webbon *et al.*, 2004) is now fairly dated and likely of low reliability, there is general agreement that the pre-breeding fox population is stable or increasing slightly (Burns *et al.*, 2000; MacDonald and Burnham, 2011). The fox is also a potential indicator for all four species of *Trichinella* reported in Europe and samples can be obtained as a result of normal pest control.

6.4. Participation in NRL QA programme

During the reporting period, Fera participated in eleven national QA exercises and achieved very good results, which are summarised in the table below.

6.4.1. Table to show results of national QA exercises conducted at Fera during FS231058 (1st April 2009 – 31st March 2012)

Distribution date 19/06/2009	No of larvae intended by NRL	4	0	5	7
	No of larvae counted at Fera	4	0	5	7
Distribution date 29/09/2009	No of larvae intended by NRL	8	4	0	6
	No of larvae counted at Fera	8	4	0	6
Distribution date 08/12/2009	No of larvae intended by NRL	4	9	0	5
	No of larvae counted at Fera	4	7	0	5
Distribution date 23/03/2010	No of larvae intended by NRL	8	6	3	0
	No of larvae counted at Fera	8	6	3	0
Distribution date 29/06/2010	No of larvae intended by NRL	9	0	0	4
	No of larvae counted at Fera	9	0	0	3
Distribution date 28/09/2010	No of larvae intended by NRL	5	3	0	7
	No of larvae counted at Fera	5	2	0	7
Distribution date 7/12/2010	No of larvae intended by NRL	0	8	4	6
	No of larvae counted at Fera	0	8	4	6
Distribution date 29/03/2011	No of larvae intended by NRL	5	7	0	4
	No of larvae counted at Fera	5	7	0	2
Distribution date 28/06/2011	No of larvae intended by NRL	3	0	6	4
	No of larvae counted at Fera	3	0	5	4
Distribution date 27/09/2011	No of larvae intended by NRL	0	8	5	0
	No of larvae counted at Fera	0	8	5	0
Distribution date 06/12/2011	No of larvae intended by NRL	4	3	0	5
	No of larvae counted at Fera	2	3	0	5

6.5. Assessment of the value of serological *Trichinella* testing methods for wildlife.

As part of this study a watching brief was kept on any developments in serological methodology and testing. Validation of serological testing in pigs is currently being examined by the CRL although no recommendations for assay have yet been made. Indirect ELISA on secretional antigens is also used in some countries (eg Belgium) for epidemiological surveillance of wild and domestic animals although these assays are not recommended as a substitute for meat inspection of individual carcasses (Gamble *et al.*, 2004). There remain several challenges to the development of serological tests in wildlife, primarily due to the low specificity of currently available assays. This is due in part to high level of sample contamination (parasitic, bacterial, viral, fungal), but also to cross-reaction with other parasites (particularly *Trichuris suis*), which leads to false positive results. False negative results are also possible due to seroconversion delays in the first stages of infection when the animal may already be infectious (Gajadhar *et al.*, 2009). For these reasons, it is generally accepted that only data for prevalence obtained with the digestion method may be considered with objectivity. Analytical sensitivity of the ELISA is, however considered to be higher

than that of the digestion method at 1 larva per 100g of tissue (Gajadhar *et al.*, 2009) and so may present an advantage compared to the digestion method when testing wildlife with a very low larval load or could be used together with alternative assays.

6.6. Outcomes of EFSA project² and its implications for *Trichinella* surveillance.

In 2008 EFSA commissioned a project to develop harmonised schemes for the monitoring and reporting of *Trichinella* in animals and foodstuffs in the European Union. This work received financial support from the UK FSA and was carried out as a collaborative project between Fera, acting as the project co-ordinator, and 11 institutes across Europe. The final report has been published on the EFSA website (EFSA, 2010) and can be accessed at

<http://www.efsa.europa.eu/en/scdocs/doc/35e.pdf>

Subsequent to the EFSA report, proposals for standardised *Trichinella* surveillance across the EU, were also published by Alban *et al.*, 2011. Both the report and publication make recommendations for data collection under current EU legislation and suggest alternatives focussing on reduced testing of individuals in low risk pig populations. The proposed scheme relies on the concept of compartmentalisation to identify subpopulations of animals at lower risk of *Trichinella* (e.g. finisher pigs that originate from controlled housing) where reduced testing could be conducted without compromising public health. Regions would be categorised into three classes based on the confidence that *Trichinella* can be considered absent in pigs above a specified design prevalence of e.g. 1 per million pigs. Hence, and as an example, the proposed scheme for a region with negligible risk in all fattening pigs would require proportionate sampling of fattening pigs from non controlled housing to demonstrate a surveillance sensitivity of $\geq 90\%$ to detect an infection of < 1 per million in combination with a wildlife testing programme to demonstrate a prevalence of *Trichinella* in wildlife of $< 0.1\%$.

Another issue addressed was the lack of a clear definition of negligible risk, especially in relation to wildlife testing, and how to demonstrate negligible risk (EFSA, 2005). Currently, a number of statistical methods are being employed and the report recommended an expert working group be set up, consisting of mathematical modellers, epidemiologists, parasitologists and statisticians to review these methods and to decide which criteria should be used to demonstrate negligible risk / disease freedom.

The report was discussed with EFSA, representatives from the EU Member States and the Commission during the 19th Meeting of the Task Force on Zoonoses Data Collection on 24 March 2010. Feedback provided by the Commission on the ideas featured in the report was positive. The Commission is considering a mandate on

² EFSA, 2010. Development of harmonised schemes for the monitoring and reporting of *Trichinella* in animals and foodstuffs in the European Union

technical assistance to lay down epidemiological criteria, which would be relevant to some of the issues discussed in the report.

6.7. Extension to FS231058

In October 2012 an extension to the current project was commissioned by the FSA with the following milestones:

Milestone	Target date	Title
01/01	31/05/2013	Complete collection and diagnostic testing of a minimum of 450 GB foxes and 150 NI foxes to provide data to satisfy disease awareness
02/01	31/05/2013	Review, as required, the testing of alternative wildlife species including, where necessary, limited sampling and laboratory diagnoses. Update recommendations on use of alternative species as required.
03/01	31/03/2013	Participate in NRL QA programme (with appropriate dates).
04/01	31/03/2013	Consider outcome of recent EFSA project and its implications for <i>Trichinella</i> surveillance. Update / consult FSA and implement any changes as agreed.

All methods used for this extension study were as reported here and a summary as well as full account of the results for this extension are detailed in Appendix 8.15.

8.15. Results for Extension to FS231058 (October 2012-March 2013) with Summary of Methods.

8.15.1.Aims

- To provide a further 6 months of wildlife carcass collection and *Trichinella* testing sufficient for maintaining disease awareness (assumed at this stage to be approximately 450 foxes from Great Britain (GB) and 150 foxes from Northern Ireland (NI) per annum) as part of a rolling programme.
- To continue to assess the value of testing other wildlife species and carry out a limited survey of alternative wildlife species where appropriate and where agreed with the FSA.
- To participate in the UK quality assurance (QA) testing programme and assess the value of serological *Trichinella* testing methods for wildlife.
- Consider the outcome of currently ongoing EFSA projects in regard to the sampling and monitoring of *Trichinella* as well as research carried out by other EU member states and provide feedback to the FSA

8.15.2. Summary of Methods

This appendix reports a study extension, which follows on from the previous Food Standards Agency (FSA) funded survey, FSA Project Code FS231058 (ex M01052) (01/04/2009 - 31/03/2012), to provide further data to support a rolling programme of disease awareness for trichinellosis in wildlife. All methods are as described in section 5 of the main report for this project. In summary: The sample size required to provide robust evidence of disease prevalence is currently determined as 450 foxes per annum from across GB and 150 foxes from NI to reflect likely fox numbers. Carcasses were collected from pest controllers, shooters and gamekeepers carrying out routine control, supplemented, where necessary, by direct culling. Areas under-represented in previous surveys were targeted to ensure wide demographic coverage. The Ordnance Survey map reference co-ordinate and the nearest town or village were recorded for all foxes and distribution was mapped frequently to allow identification of under-represented areas.

All muscle tissue was removed from fox carcasses at the Food and Environment Research Agency (Fera) apart from the NI tissue samples, which were removed at Agri-Food and Biosciences Institute, Northern Ireland (AFBINI) before dispatch by courier to Fera, York with their relevant paperwork. Samples were pooled in batches of 20 for digest using the methodology published by Zimmer *et al.*, 2008, based on EC 2075/2005, the standard for testing domestic pigs but optimised for fox muscle.

Cetaceans and pinnipeds were tested as and when samples became available through the UK Cetacean Strandings Investigation Programme, which is jointly funded by Defra, the Welsh Assembly Government and the Scottish Government (www.ukstrandings.org).

All procedures were conducted to standard Fera/JCOP protocols. Samples were tested within 28 days of death.

Literature searches and contacts established through the network of National Reference Laboratories were used for updates on the occurrence of *Trichinella* in wildlife species in other European countries. Any European Union (EU) relevant findings and official recommendations were brought forward for discussions with the FSA to ensure EU compliance and to support the ongoing application for '*Trichinella*-negligible' status.

Data was summarised in monthly reports as well as this final report as an appendix to the full report prepared under Project Code FS231058 (ex M01052) (01/04/2009 - 31/03/2012).

8.15.3. Results and Discussion

***Trichinella* in Foxes**

Between 1st October 2012 and 31st March 2013 a total of 627 foxes from GB were collected of which 578 were tested for *Trichinella*. All foxes were found to be negative for *Trichinella*.

A monthly summary for GB fox carcasses collected for the study period, 1st October 2012 – 31st March 2013, is given in Table 1. Figure 1 shows a map of the collection (or kill) locations for the GB foxes tested for *Trichinella* infection. Individual data for foxes tested under this extension to FS231058 are presented in Table 2.

Tested fox data (GB) are also summarised for gender (Table 3), age (Table 4), condition (Table 5) and weight (Table 6). Overall, and where recorded, approximately 42% of GB tested foxes were female, were predominantly young adults (25% were aged and 1% juvenile), in good condition (27% were fair and only 3% classed as in poor condition) and the average fox weighed 6.2 kg.

Between 1st September 2012 and 31st March 2013 a total of 181 foxes from NI were collected, of which 177 were tested for *Trichinella*. All foxes were found to be negative for *Trichinella*. Collection (or kill) locations for all NI foxes collected for *Trichinella* infection under this extension to FS231058 are mapped in Figure 1 with individual data for tested foxes shown in Table 7.

A monthly summary of NI fox collections broken down for each month is given in Table 1. NI tested fox data is summarised for gender (Table 8), age (Table 9), condition (Table 10) and weight (Table 11). Overall, and where recorded, approximately 54% of NI tested foxes were female, were predominantly adults (8% juvenile) and where further classified, only young adults were recorded. Most foxes

were in good condition (21% were fair and 9% classed as in poor condition) and the average fox weighed 5.5 kg.

When data collected under this extension to FS231058 is added to previous studies (1st October 1999 – 31st March 2012) 6505 GB foxes have been tested. No *Trichinella* positive foxes have been found in GB. When the current NI data is added to previous studies (2003/4 and January 2007 – March 2012), a total of 1190 foxes have been tested. Only two of these NI foxes have presented as positive to *Trichinella* giving a prevalence of <0.2%. No national survey data exists on fox numbers in NI so it is not possible to estimate the total number of positive animals in NI.

***Trichinella* in alternative wildlife species**

All data not presented in the main report is detailed here. Between 8th March 2013 and 24th April 2013, a total of 5 cetaceans (2 harbour porpoise, 2 common dolphins and 1 Pilot whale) and 4 pinnipeds (4 grey seals) were tested for *Trichinella*. The individual animals and further details are listed in Table 12. All samples tested negative.

Participation in NRL QA programme

Since reporting FS231058, Fera has participated in five further national QA exercises and achieved very good results, which are summarised in Table 13.

Outcomes of EFSA project and its implications for *Trichinella* surveillance

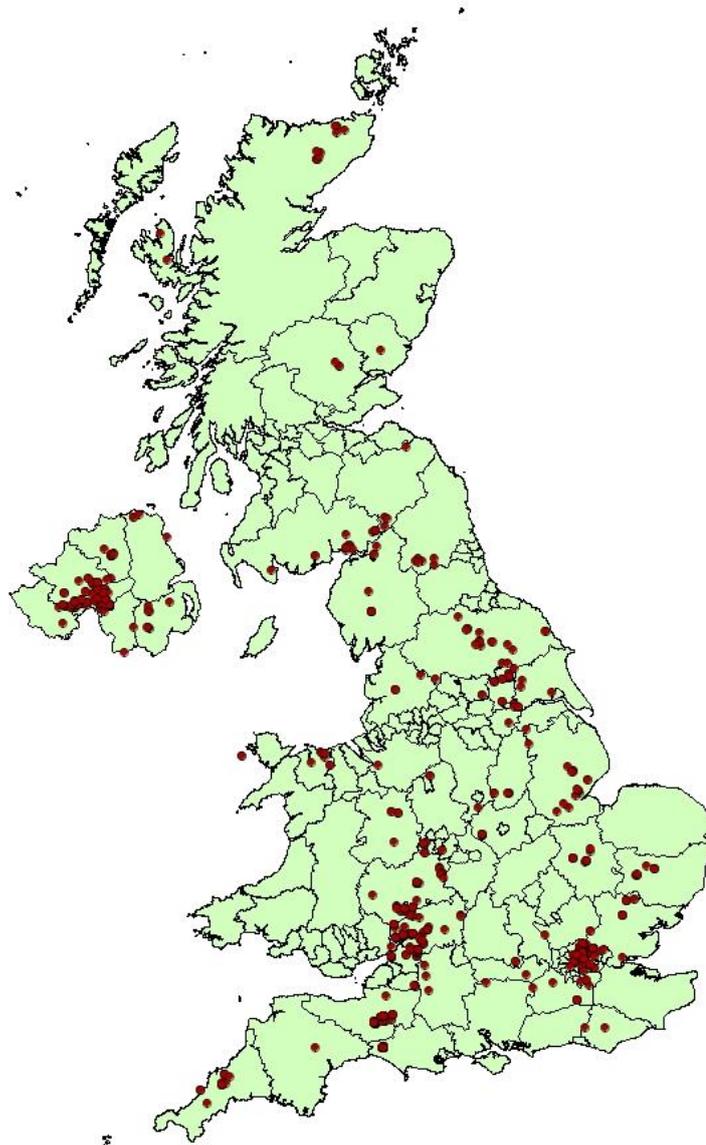

Nothing further to report.

Table 1. Number of foxes collected for extension of FS231058 per month

Year	Month	Foxes Collected GB	Foxes Collected NI
2012	9		29
2012	10	16	51
2009	11	109	22
2012	12	119	23
2013	1	156	16
2013	2	119	20
2013	3	108	20
Total		627	181

Figure 1. Location of fox collection points for FS231058 extension

Map of collection points for the 578 GB and 177 NI samples collected and analysed for *Trichinella* for the period 1st September 2012 – 31st March 2013. Individual dots may represent more than one fox collected from that location and the size of catchments for each collection point varies, depending on the geographic location and estate size

Extension to FSA Contract FS231058
01/09/2012 to 31/03/2013

Table 2. Raw data for GB foxes tested over the period 1st September 2012 to 31 March 2013 to show sex, age, condition and weight
