## SUMMARY

1. Individual samples consisting of a range of commonly consumed foods were collected in 2007. In the first phase of this work, 101 of these samples were selected for the analysis of brominated contaminants. The concentrations of selected individual polybrominated dibenzo-*p*-dioxins (PBDDs), polybrominated dibenzofurans (PBDFs), polybrominated diphenyl ethers (PBDEs) and polybrominated biphenyl (PBBs) congeners were measured and are reported for each sample. Additionally, concentrations of hexabromocyclododecane (HBCD) diasteriomers and tetrabromo bisphenol A (TBBPA) are also reported. In the second phase of this work a smaller set of 14 samples, targeted largely from the outcome of the first phase results were analysed for the same set of determinands.
2. The reporting limits quoted for the PBDD/Fs were typically as low as sub-nug/kg (parts per trillion) levels on a fat weight basis and typically as low as 0.01 μg/kg for PBDE and PBB measurements. Measurement uncertainty estimates calculated as per the Eurachem guide have also been reported.
3. Methodology for the analysis of three other Brominated Flame Retardants (BFRs) - Hexabromobenzene (HBB), Bis(246-tribromophenoxy)ethane (BTBPE), and Decabromodiphenylethane (DBDPE) was developed and validated. This methodology has been applied to the analysis of the above food samples. Typical reporting limits for these compounds range from 0.01 μg/kg for HBB to 0.06 μg/kg for DBDPE, the higher values reflecting lability and the current widespread usage of these chemicals. The limits for the HBCD diasteriomers and TBBPA were in a similar range to these compounds.
4. The toxic equivalents (TEQ) approach to estimating toxicity that is normally used for chlorinated dioxin (PCDD/F) and PCB contamination of food has been used here, where applicable. Thus toxic equivalent factors (TEFs) corresponding to the analogous PCDD/Fs and PCBs have been used to generate TEQs for PBDD/Fs and PBBs for each sample. The limitations of this approach must be recognised in that the TEFs used are not specific to

PBDD/Fs and PBBs and thus provide only an indication of toxicity. The approach is an interim measure until a comprehensive set of valid TEFs become available for these compounds.

5. PBDEs were the most frequently detected contaminant and occurred in all the samples. PBDFs were detected more frequently than PBDDs and at higher levels. Some PBDD and PBB congeners, were not detectable in any of the samples. Of the emerging BFR contaminants for which methods were developed, HBB and DBDPE were not detected at all, whilst BTBPE occurred in some samples.  $\alpha$ -HBCD was the most frequently detected of the HBCD compounds and was most predominant in fish. Lower levels of the  $\beta$ - and  $\gamma$ -diasteriomers were also detected in a few samples, but TBBPA was not detected at all. The levels reported of the various contaminants that were measured in this work are consistent with the limited available literature observations made for the various foods as well as the environmental and biological characteristics of contaminant bio-accumulation.

## GLOSSARY

$\Sigma$ PBDD/F TEQ	Sum of WHO-TEQ for individual PBDD/PBDF congeners
$\Sigma$ non- <i>ortho</i> PBB TEQ	Sum of WHO-TEQ for individual non- <i>ortho</i> PBB congeners
BDE	Brominated Diphenylether
BCR	Community Bureau of Reference
BFR	Brominated Flame Retardant
BTBPE	Bis(246-tribromophenoxy)ethane
CRM	Certified Reference Material
DBDPE	Decabromodiphenylethane
GC-HRMS	Gas chromatography - high resolution mass spectrometry
HBB	Hexabromobenzene
HBCD	Hexabromocyclododecane
HPLC-MS/MS	LC-MS in multiple reaction monitoring mode
IUPAC	International Union of Pure and Applied Chemistry
LC-MS	High Pressure Liquid Chromatography - mass spectrometry
PCB/PBB	Polychlorinated biphenyl/ Polybrominated biphenyl
PBDE	Polybrominated Diphenylether
PBDD/F	Polybrominated dibenzo- <i>p</i> -dioxin/ furan
PCDD/F	Polychlorinated dibenzo- <i>p</i> -dioxin/ furan
PTMI	Provisional tolerable monthly intake
PTV	Programmed temperature vaporisation
RM	Reference Material
SCF	EU Scientific Committee on Food
TBBPA	Tetrabromo Bisphenol A
TDI	Tolerable Daily Intake
TDS	Total diet survey
TEF	Toxic Equivalence Factor
TEQ	Toxic equivalence
WHO	World Health Organisation
WHO-TEF	Toxic Equivalence Factor
%U	Percentage Uncertainty

## INTRODUCTION

1.1 Brominated contaminants commonly refer to a range of additive and reactive brominated flame retardant chemicals (BFRs), and brominated dioxins and furans (PBDD/Fs). BFRs are used specifically to slow down or inhibit the initial phase of a developing fire. Polybrominated diphenylethers (PBDEs), polybrominated biphenyls (PBBs), hexabromocyclododecane (HBCD), tetrabromo bisphenol A (TBBPA) are mass produced BFRs that are incorporated into a number of commonly used commercial materials such as plastics, rubbers, textiles and electronic components. Materials incorporating BFRs find wide-ranging applications from furniture foam and textiles to aircraft, automobiles and electronic equipment (1). These applications have undoubtedly resulted in a reduction in human fatalities (2,3) and figures of 20% reductions in fire deaths directly attributable to flame retardants have been quoted. BFRs are either mixed with ingredients when materials are produced (e.g. PBDEs) or in some cases are chemically bonded (e.g. TBBPA). As these are both open-ended applications, the BFRs are available to diffuse out of materials into the environment, and this can occur over the lifetime of the material - during manufacture, use, and disposal. The occurrence of BFRs in environmental compartments such as water, sediments and biota (1) accompanies an increasing amount of evidence that suggests that these chemicals may cause potential detrimental human health effects (1,4,5). PBDEs and PBBs have recently been added to the Stockholm Convention list of substances of very high concern

1.2 There is very little information on the occurrence of BFRs (other than PBDEs) and PBDD/Fs in food. This is perhaps unsurprising given the relatively recent recognition of the global environmental distribution of these pollutants (1). Additionally, analytical accessibility to reliable measurement of these contaminants has also limited the volume of available data. Unlike chlorinated pollutants, BFRs and brominated dioxins are particularly susceptible to degradation, interconversion and adsorption during analysis and these are important considerations in any analytical methodology used for reliable measurement. This report addresses the issues raised above and

describes the analytical methodology used as well as current data on the levels of these contaminants in a range of commonly consumed foods. Additionally methodology for the analysis of three further BFR compounds - Hexabromobenzene (HBB), Bis(246-tribromophenoxy)ethane (BTBPE), and Decabromodiphenylethane (DBDPE) was developed and validated and is also described. These compounds have been identified by the European Food Safety Authority (EFSA) as emerging BFRs that could be included in future monitoring programmes (6). This methodology has been applied to the analysis of the above food samples.

1.3 The structural similarity of some BFRs e.g. PBDEs and PBBs, to dioxins and PCBs and their consistent detection in biota and environmental media are evidence of the persistent nature of these contaminants. Emerging toxicological data shows that PBDEs can cause liver and neurodevelopmental toxicity and affect thyroid hormone levels. In recent years the EU has carried out a comprehensive risk assessment under the Existing Substances Regulation (793/93/EEC) of commercial PBDE products (7). The outcome was a ban on the use of PentaBDE and OctaBDE since 2004. The situation with regard to another mixture - decaBDE remains fluid - in 2008, the European Court of Justice (ECJ) annulled the exemption to the EU Directive on the Restriction of the Use of Certain Hazardous Substances in Electrical and Electronic Equipment 2002/95/EC, commonly referred to as the Restriction of Hazardous Substances Directive or RoHS Directive as of 30 June 2008 that was granted in 2005 for Deca-BDE.

1.4 PBDD/Fs are inadvertent by-products of incineration processes and have physico-chemical properties that are similar to their chlorinated analogues. They originate from similar anthropogenic sources as chlorinated dioxins, such as incineration, or chemical manufacture e.g. PBDD/F are formed as by-products during the manufacture of PBDEs. Studies of incineration processes (1,8) show that the formation of these compounds are consistent with “de novo” hypothesis and are thus governed by the occurrence of bromine or chlorine sources in incinerator feed. There are studies (1,9,10) to show that the incineration of products containing BFRs as well as thermolysis of BFR

material such as PBDEs is an important source of PBDD/F emissions. PBDD/Fs can also be formed from PBDEs, during thermal processing procedures such as extrusion, moulding and recycling, and degradation (1). It has also been demonstrated that PBDD/Fs can be formed during ultra-violet irradiation of decabromodiphenyl ether (11). Recently, there have been reports that some lower brominated PBDD congeners (tri- tetra-) may be produced through biogenic formation via naturally occurring bromophenols in the marine environment and bio-accumulate in some marine species (12,13). As the utilisation of BFRs continues to increase, a corresponding increase in PBDD/Fs levels can be expected. Studies on the toxicity of PBDD/Fs are limited but both, in vivo and in vitro studies demonstrate AhR agonist properties and dioxin-like effects (14,15). Although there are a number of methods reported for the analysis of dioxins, PCBs and PBDEs (1,16-19) very few methods exist for the determination of PBDD/Fs (16,19-21). To date there is very little available data on the occurrence of these compounds in food.

1.5 A major obstacle to the risk assessment of human exposure to brominated contaminants is the acute shortage of reliable occurrence data. This is particularly true for contaminants such as PBDD/Fs where analytical accessibility is limited due to the difficulties encountered in making reliable measurements. Other aspects of this issue are the fact that food matrices are more analytically challenging than environmental matrices (for which relatively more data is available), and the requirement for measurements to be sufficiently sensitive to make the risk assessment meaningful. However, in the UK, the Food Standards Agency has recently commissioned three studies on brominated contaminants – one investigating levels of occurrence in the food groups of the total diet study for 2004 and the associated human dietary intakes (22), and the others, investigating levels in fish (23) and shellfish (20, 24).

1.6. General observations from the TDS study showed that PBDEs, particularly congeners 47, 49, 66, 99, 100, 153, 183 and 209 were detected in most of the food groups. In general, lower brominated congeners such as PBDE 47 were most abundant in fish, whilst the higher brominated congeners

were more abundant in meat. Other PBDEs, PBDFs, PBBs and HBCDs were detected less frequently, and PBDDs and TBBP-A was not found above the limit of detection in any food group. The greater frequency of detection of PBDFs relative to PBDDs reflects the environmental occurrence and emission profiles for brominated dioxins and furans, which both show higher levels of the furans. Therefore a wider range of PBDF congeners were detected in fruits, green vegetables and sugars and preserves. Other non-2378 bromo substituted congeners were also observed although due to lack of standards it was not possible to quantify these. Among the HBCD congeners measured, alpha-HBCD was detected in half of the food groups, being highest in fruit, vegetables and meat. Beta- and gamma-HBCD were found less frequently, at lower levels and only in fruit and vegetables. The resulting average adult dietary intakes from the whole diet were estimated at <5.9 ng/kg bodyweight/day for total PBDEs, <5.9 ng/kg bodyweight/day for total HBCDs, <1.6 ng/kg bodyweight/day for TBBP-A, and <0.4 pg TEQ/kg bodyweight/day for brominated dioxins. The estimated total adult dietary intake of brominated dioxins was comparable with that found in Japan (1.4 pg TEQ/kg bodyweight/day) (19).

1.7 The studies on fish and shellfish (23,24) investigated 48 and 60 composite samples respectively and showed greater frequency of detection of the different analytes apart from TBBP-A which was not detected in any sample. As with the TDS, the PBDEs were detected in most of the samples as was alpha-HBCD (apart from the canned products). Lower brominated dioxins and furans were also detected in a number of samples, with tribromo analogues occurring at significant levels particularly in shellfish. This is an important observation as tri-brominated dioxins and furans may have a greater toxicological significance than their chlorinated counterparts (25).

1.8 This study will complement and extend the available knowledge on the occurrence of these contaminants in food, by providing data for a wide range of individual foods that are commonly consumed. This will allow a current and more realistic estimate of the dietary intake of different population groups

and provide a better assessment of the health risk arising from the ingestion of these contaminants.

## **EXPERIMENTAL**

### **Sampling**

2.1 In the first phase of sampling, 101 samples of various foods ranging from fish and meat to vegetables, dairy products and processed foods were collected between June and August 2007 by Ventress Technical Ltd. (26). On receipt at the laboratory each sample was given a unique laboratory reference number and the sample details logged into a database. The samples were stored frozen prior to analysis. Data for some of the analytes, generated for these samples was used to target a second smaller set of 14 additional foods.

2.2 Details of the sampling plan (including location of the sampling sites) constructed in conjunction with the FSA have been reported elsewhere (26).

2.3 The composite samples were freeze-dried and the resulting powders were thoroughly mixed before taking sub-samples for analysis. The analytical methodology used for the measurement of PBDD/Fs, PBDEs, PBBs by GC-MS and HBCD and TBBPA by LC-MS/MS is described in the following paragraphs. The methodology developed for the analysis of the three EFSA prioritised flame retardants – HBB, BTBPE and DBDPE – used GC-MS and is described later.

### **Fat Determinations**

2.4 Fat determinations were performed by a UKAS (ISO 17025) accredited laboratory on sub-samples of the freeze-dried and homogenised samples using a standard method (27).

### **Analytes – GC-MS determinations**

2.5 The following analytes were determined:

Brominated dioxins - 2,3,7-T<sub>3</sub>BDD, 2,3,8-T<sub>3</sub>BDF, 2,3,7,8-Br substituted PBDD/Fs: tetra – hexa brominated congeners (note that this includes only 1 hexa-Br substituted furan as no standards were available for the other 3 congeners)

PBDE congeners: IUPAC numbers 17, 28, 47, 49, 66, 71, 77, 85, 99, 100, 119, 126, 138, 153, 154 and 183.

PBB congeners: IUPAC numbers 15, 49, 52, 77, 101, 126, 169, and 153.

PBDE 209 and PBB 209 (deca bromo compounds)

HBB, BTBPE and DBDPE

#### **Analytes – LC-MS/MS determinations**

$\alpha$ -HBCD,  $\beta$ -HBCD and  $\gamma$ - HBCD, TBBPA

#### **Materials**

2.6 Reference standards for PBDD/Fs, PBBs, PBDEs, HBB, BTBPE, DBDPE and  $^{13}\text{C}_{12}$  materials for use as internal standards were sourced from either Cambridge Isotope Laboratories (Andover, MA, USA) or from Wellington Laboratories (Guelph, Ontario, Canada) as solutions in n-nonane, iso-octane, methanol or toluene with a specified 10% tolerance on concentration. Deca-BB was obtained as an iso-octane solution from Accustandard and deca-BDE was obtained as a toluene solution from Wellington.

2.7 The PBDD/F internal standard solution contained nominal concentrations of 10 ng/ml each of five  $^{13}\text{C}_{12}$  labelled 2,3,7,8-substituted internal standards (one each for tetra- and penta-Br substituted dioxin and furan, and one hexa-Br substituted dioxin). The internal standard solution for the PBBs and PBDEs contained nominal concentrations of 100 ng/ml of  $^{13}\text{C}_{12}$  labelled PBBs (IUPAC numbers 52, 77 126 and 153), 100 ng/ml of  $^{13}\text{C}_{12}$  labelled PBDEs (IUPAC numbers 28, 47, 99, 153, 154 and 183) and 300 ng/ml of  $^{13}\text{C}_{12}$  labelled Deca-BDE.

2.8. The internal sensitivity standard solution used for PBDD/Fs, PBBs and PBDEs contained  $^{13}\text{C}_{12}$  -PCB 202 and  $^{13}\text{C}_{12}$  -PBDE 139 at a nominal concentration of 100 ng/ml. All internal and sensitivity standard solutions were prepared in n-nonane.

2.9. Dichloromethane, methanol, toluene, hexane and n-nonane were

purchased as doubly glass distilled (Rathburn, Scotland) and assessed for lack of contamination before use.

2.10. Alumina (Sigma Chemical Company, USA) was activated by baking overnight in a muffle furnace at 450° C. All other chemicals employed were Analytical Reagent grade materials.

2.11. Reagents, including base-modified and acid-modified silica gel, were prepared as previously reported (16,20) and were assessed for contamination prior to use.

2.12. All equipment was scrupulously cleaned and thoroughly rinsed with dichloromethane prior to use. Care was taken to avoid direct sunlight and airborne contamination of containers was minimised by keeping vials capped even when empty and covering flasks and concentration tubes with cleaned aluminium foil.

### **Extraction and purification**

2.13. The extraction, purification and analysis of samples for PBDD/Fs, PBBs and PBDEs was carried out as previously reported (16,20). In brief, aliquots of the samples were fortified with the internal standard solutions described in 2.7 and extracted by solvent action.

2.14. The crude extract obtained was quantitatively transferred into an apparatus containing modified silicas followed by activated carbon on glass fibres where the analytes were fractionated on the basis of their planarity.

2.15. The two fractions containing i) ortho-PBBs and PBDEs, ii) non-ortho-PBBs and PBDD/Fs were purified using acid and base hydrolysis and activated alumina.

2.16. Where required, fractions were further purified using acid hydrolysis

and alumina. The extracts were concentrated and the appropriate sensitivity standard was added to each fraction prior to instrumental analysis.

#### **GC-HRMS determination of PBDD/Fs, PBDEs, PBBs and deca-BB/BDE**

2.17. GC-high resolution mass spectrometry was performed on either one of two Micromass Autospec Ultima instruments fitted with a Hewlett Packard 6890N gas chromatograph and a CTC Analytics PAL GC autosampler or a CTC A200SE autosampler. The gas chromatograph was fitted with a 60m J&W DB-5 MS fused silica capillary column. The GC-MS interface was set to 280°C. Injections were made with a PTV injector using a temperature programme which consisted of a 3 minute isothermal period at 60°C followed by heating at 12°C/sec to 320°C, hold for 3 min and then at 12°C/sec to 350°C. For the PBDD/Fs and non-ortho PBBs, the oven temperature programme consisted of a 5 minute isothermal period at 80°C followed by heating at 14°C/min to 220°C for 1 min, then at 3°C/min to 280°C for 1 min, then 6°C/min to 310°C for 9 min, followed by 20°C/min to 330°C with a final isothermal period of 3 min. Electron ionisation was used and the mass spectrometer was operated at a resolution of 9000 - 10000 (based on peak width at 10% of peak height) with focussing optimised prior to each run. Selected ion monitoring was employed, using the two most intense ions in the molecular ion cluster for each homologue. These conditions were used to monitor PBDD/Fs and non-ortho-PBBs in one run, with the ortho substituted PBBs and PBDEs measured in a second run using the following oven temperature programme: 4 minute isothermal period at 60°C followed by heating at 11.3°C/min to 150°C for 1 min, then at 20°C/min to 230°C for 1 min, then 2°C/min to 270°C for 1 min, then 10°C/min to 310°C for 7 min followed by 20°C/min to 330°C with a final isothermal period of 4 min.

2.18. Decabromo analytes were measured in a separate run (20) using a 15 m ZB5-MS column (Zebron, Phenomenex) operated using the following oven temperature programme: 3 min at 60°C, 20°C/min to 205°C for 21 min, then 66°C/min to 325°C for 10 min. The PTV injector in constant flow mode used the following transfer programme: 3 min at 60°C, 12°C/sec to 320°C for 3

min, then 12<sup>0</sup>C/sec to 350<sup>0</sup>C.

### **Data handling**

2.19. Data reduction for all GC-MS analyses, and processing to calculate the mass of each compound present was performed using Masslynx 3.5 software supplied by Micromass (Waters). These data were transcribed to Microsoft Excel for collation and quantitation of concentration data.

### **Quality control (GC-MS)**

2.20. The methodology used for the determination of PBDD/Fs, PBDEs and PBBs has been accredited (UKAS) to the ISO17025 standard. The scope of the accreditation covers all congeners except deca-BDE/BB. There are no universal acceptance criteria for data quality, so quality control for the accompanying data has followed the criteria currently used for chlorinated dioxins and PCBs for which acceptance criteria are published (28). Further, the methodology used for these brominated analytes is essentially the same as that used for chlorinated dioxins and PCBs – featuring the extensive use of <sup>13</sup>Carbon labelled analyte surrogates and measurement by high resolution mass spectrometry. Basic method quality data for PBDEs and PBDD/Fs using essentially the same method as that successfully used over several years for chlorinated dioxins and PCBs has been published before (16).

2.21. The GC-MS analytical run of each batch of purified sample extracts was preceded by the analysis of a standard reference solution used to check system performance and calibration validity. The reference standard solution was also analysed during and at the end of the analytical run. All integrated chromatograms were scrutinised to assess chromatographic peak shape, resolution and signal-to-noise. Additionally, lock-mass traces were examined for evidence of ionisation suppression and isotope ratios were compared with theoretical abundances.

2.22. GC-MS data were acceptable or better for all congeners in all samples.

2.23. Sample extraction and purification was carried out in batches that included a full method blank. The blank was assessed for internal standard recoveries and for the presence of native analytes.

2.24. In the absence of reference materials for the brominated dioxins and PBBs, a number of different food matrices ranging from milk to fish were fortified with native analytes and analysed using the methodology described. Results obtained for these were in good agreement with fortification levels. Additionally a RM commonly used for chlorinated dioxins and PCB analysis (29) was included in sample batches. Where analytes were detectable (PBDEs and PBBs), data for the reference material analysed shows consistency during the course of the work.

2.25. FERA regularly participates in inter-comparison exercises, where these are available, for e.g. most recently, in 2003, 2005, 2007 and 2009 rounds of the inter-comparison exercise – “Dioxins in Food” (30-32, the final report for the 2009 round is not yet available). Results reported by the laboratory were in good agreement with consensus data. There are currently no exercises running for brominated dioxins or PBBs in food, but there is an exercise for the determination of PBDEs in biota (33). For participation to date, results reported by the laboratory were in excellent agreement with consensus data (Exercise 618 round 37). Additionally, the “Dioxins in Food” inter-comparisons for 2005, 2007-2009 have also included measurements for PBDEs. Results reported for food-based matrices such as fish oil, butter-oil, fish and poultry were in agreement with consensus data.

### **LC-MS/MS determination of HBCD and TBBPA**

2.26 As reported previously (23) the analyses were carried out in duplicate. Four aliquots of each sample were taken. Two of these were spiked with internal standard (10 ng each of  $^{13}\text{C}$   $\alpha$ HBCD,  $^{13}\text{C}$   $\beta$ HBCD,  $^{13}\text{C}$   $\gamma$ HBCD and  $^{13}\text{C}$  TBBPA) and the four analytes (10 ng each of TBBPA,  $\alpha$ HBCD,  $\beta$ HBCD, and  $\gamma$ HBCD). The other two portions were spiked with the internal standard.

Procedural blanks and an in-house reference material were run with each batch of samples. The samples were left to stabilise for 30 min prior to extraction. High lipid content samples were mixed with anhydrous sodium sulphate (50 g) and hexane:dichloromethane, 60:40 (v/v) (200 ml) was added. The mixture was homogenised using an Ultra Turrax for 1 min, left to stand for a further 10 min and 60 g of acid modified silica was added. The slurry was homogenised for 5 min, filtered and the filtrate collected. The silica residue was washed with hexane:dichloromethane, 60:40 (v/v) (50 ml) and allowed to stand for 15 min.

2.27 The filtrate was transferred to a turbo-vap tube and reduced in volume to approximately 0.5ml. This was then transferred to a glass vial and evaporated to ~5 µl. The extract was reconstituted to 150 µl (using 100 µl of methanol + 30 µl of water) and transferred to a glass vial for HPLC-MS/MS determination. Analysis was carried out using the chromatographic conditions reported earlier (45). The analytes were detected by MS/MS in multiple reaction monitoring mode (MRM) mode (34).

### **Quality control (HPLC-MS/MS)**

2.28 The methodology used here for the determination of individual HBCD steriomers and TBBPA has been peer reviewed and published (34).

2.29 <sup>13</sup>Carbon labelled surrogates of each of the 4 analytes were used as internal standards for quantification. This allowed more accurate determination of analytes and gave better precision of measurement which was typically of the order of 16% (RSD) (45). Additionally most determinations were carried out in duplicate with good agreement.

2.30 The method limit of determination for HBCD isomers and TBBPA was calculated using the instrument response to the lowest calibration standard and the levels of these analytes detected in the method blanks. The limits of determination were typically in the range of 0.01 to 0.1 µg/kg for the analytes

on a whole weight basis, depending on the matrix. Analytical recoveries were generally within the range of 60 - 120%.

2.31 There are no certified reference materials available for HBCD or TBBPA analysis in food matrices. However, aliquots of all the samples analysed were fortified with native analytes and the concentrations of recovered analytes measured, were in good agreement with fortification levels. Additionally a fortified in-house reference material was also analysed regularly with the samples and returned values that were in good agreement with fortification levels.

2.32 The measurement by HPLC-MS/MS was linear (regression coefficient > 0.99) for all analytes over the concentration ranges reported.

#### **Determination of HBB, BTBPE and DBDPE**

2.33 Analytical methodology was developed during the course of this work for the determination of Hexabromobenzene (HBB), Bis(246-tribromophenoxy)ethane (BTBPE), and Decabromodiphenylethane (DBDPE). The methodology was based on internal standardisation using <sup>13</sup>Carbon labelled surrogates of the three compounds and measurement by high resolution GC coupled to high resolution MS.

2.34 In the extraction stage, 5 to 10 g aliquots of the freeze-dried and homogenized sample, fortified with a known amount (in typically 50 µL) of <sup>13</sup>C<sub>12</sub> labeled surrogates and equilibrated, were pre-treated with 50g of H<sub>2</sub>SO<sub>4</sub> modified silica (1:1, w:w) in 100ml of n-hexane. The mixture was frequently agitated to prevent setting and continuously swirled to ensure good contact between the matrix and the suspended acid. The mixture was quantitatively transferred to the top of a multi-layer column (70 x 600 mm) packed from top to bottom with; 30 g of anhydrous sodium sulphate, 25 g of H<sub>2</sub>SO<sub>4</sub> modified silica gel as described above, 50 g of base modified silica gel (YMC Gel, Kyoto, Japan; prepared by mixing in the ratio 3:1, 5M KOH in methanol:silica and allowing evaporation of methanol and stabilization for 24 hours), 10 g of sodium sulphate and silanised glass wool. The column was eluted with hexane

(100 mL) and dichloromethane:hexane (40:60 v/v, 200 mL). The eluate was quantitatively split into two equal parts, one of which was concentrated and solvent exchanged to ~1ml hexane and treated with concentrated H<sub>2</sub>SO<sub>4</sub>, followed by a wash with de-ionised water. The treated extract was then chromatographed on a 5.6g activated Florisil™ (activated by baking at 150°C for >16h) column which was eluted with 10 ml of hexane to waste, followed by 60ml of dichloromethane:hexane (40:60 v/v). This fraction was concentrated and solvent exchanged to the volume of the internal sensitivity standard (25 µl of nonane containing <sup>13</sup>C<sub>12</sub> -PBDE 139 at a nominal concentration of 100 ng/ml)

2.35 The extracts were analysed by GC-high resolution mass spectrometry performed on a Micromass Autospec Ultima instruments fitted with a Hewlett Packard 6890N gas chromatograph and a CTC A200SE autosampler. The gas chromatograph was fitted with a 15 m ZB5-MS column (Zebtron, Phenomenex), operated using the following oven temperature programme: 3 min at 60°C, 20°C/min to 205°C for 21 min, then 66°C/min to 325°C for 10 min. 10 µl injections were made with a PTV injector in constant flow mode using the following transfer programme: 3 min at 60°C, 12°C/sec to 320°C for 3 min, then 12°C/sec to 350°C. The GC-MS interface was set to 280°C. The mass spectrometer used electron ionisation and operated at a resolution of ~ 7000 - 8000 (based on peak width at 10% of peak height) with focussing optimised prior to each run. Selected ion monitoring was employed, using the two most intense ions below m/z 850 for each analyte.

2.367 As for the PBDD/F measurements rationalization of the mass spectral output and processing to calculate the quantity of each compound present was performed using Masslynx 3.5 software supplied by Micromass. These data were transcribed to Microsoft Excel for collation and quantitation of concentration data.

### **Quality Control**

2.37 In general terms, the extraction and purification methodology described above is similar to, and is based on the methodology used at FERA/CSL (16)

for dioxin analysis (without the use of activated carbon), in that it uses cold solvent extraction and acid hydrolysis of the food matrices, followed by purification using adsorption chromatography and measurement by HRMS. The use of these techniques has been peer-reviewed and the methodology has been used successfully over many years for the measurement of dioxins and PCBs.

2.38 The use of high resolution mass spectrometry (HRMS) confers a high degree of measurement specificity as well as sensitivity. Method limits of detection are typically of the order of ~0.01 µg/kg for HBB and BTBPE and 0.06 µg/kg for DBDPE on a whole weight basis. The use of <sup>13</sup>Carbon labelled surrogates for each of the 3 compounds is a practice that is well-established for environmental contaminant analysis and gives a high level of method control. This results in good reproducibility and replicate measurements on the same matrix have shown an average precision of around 10 % as defined by the co-efficient of variation. The accuracy of the measurement has been investigated by the successful analysis of food matrices fortified at different levels, returning concentrations that were in agreement with the fortified values. There are no available reference materials (RMs) for these compounds, but an in-house reference material (fortified sunflower oil) investigated during the course of this work yielded data that was consistent with expected levels.

2.39 Analytical recoveries for HBB, BTBPE and DBDPE were based on the incurred <sup>13</sup>Carbon labelled surrogates, and were typically within the range 40-80%, which reflects the lability of highly brominated organic molecules. Concentrations reported here are of course, corrected for recovery.

2.40 The measurement by GC-HRMS was linear (regression coefficient > 0.995) for all the three analytes over the concentration ranges reported.

## **RESULTS AND DISCUSSION**

3.1. A list of samples including a description and CSL sample number is

given in Table 1.

3.2. PBDD/F concentrations are given in Table 2, non-ortho PBBs in Table 3, ortho-PBB in Table 4 and PBDEs in Table 5. Data were rounded to two decimal places for all analytes. Measurement uncertainty has been estimated for PBDD/Fs, PBDEs and PBBs as per the Eurachem guide (35). The estimate takes into account contributory parameters such as the individual uncertainties associated with fat content, sample size, results of the analysis of fortified samples, and limits of detection. Typical uncertainties, for example, for PBDFs are of the order of 20% at the 1 ng/kg fat level, but can rise to around 200% at the limit of detection (typically 0.01 ng/kg fat, but dependent on the fat content and sample size). In perspective, this is the same degree of uncertainty achieved by CSL in recent international inter-comparison exercises for dioxins and PCBs (30-33) where measurements were made at similar concentrations and results reported by the laboratory were in good agreement with consensus data. For HBB, BTBPE and DBDPE, the uncertainty for detected compounds was higher, typically around 50% and rising to ~250% for values near the LOD. These are provided in the corresponding tables (Tables 6-7), as are analytical tolerance estimates for HBCD and TBBPA.

3.3. The reporting limits quoted (as “<”) for all analytes was the limit of determination that prevailed in that instance. The limits for the PBDD/Fs were typically as low as sub-ng/kg (parts per trillion) levels on a fat weight basis, and typically as low as 0.01 µg/kg for PBDE and PBB measurements. Corresponding limits for HBB and BTBPE were 0.01 µg/kg on a whole weight basis rising to 0.06 µg/kg for DBDPE. A very similar range of reporting limits was achieved for the analytes measured by LC-MS, HBCD and TBBPA. In general, for all analytes, the limits are consistent with those reported in earlier work and were generally better, or at least equivalent to those reported in the literature.

3.4. The data in Tables 2 and 3 is supplemented by the addition of toxic equivalent values (TEQs) for the PBDD/Fs and the non-ortho-substituted

PBBs. The use of analogous chlorinated dioxin and PCB toxic equivalent factors (TEFs) (36) to estimate toxicity (TEQs) arising from PBDD/Fs and non-ortho PBBs is limited in that it provides an indication of the likely TEQ of the samples. This approach has been proposed (15) as both chlorinated and brominated dioxins show similar biological effects such as induction of aryl hydrocarbon hydroxylase (AHH)/EROD activity and other toxic responses such as wasting syndrome, thymic atrophy and liver toxicity in a range of test animals (25). However the approach should be recognised as an interim measure until reliable TEF values that cover all the congeners that show dioxin-like toxicity become available. The toxicities for these compounds continue to be studied (14) and potencies of some congeners, relative to 2,3,7,8-TCDD have been reported (14, 25, 37-38) in the literature.

3.5 Measurement uncertainty for individual PBDD/Fs, and PBBs with a WHO-TEF value as reported in Tables 2-3 has been extrapolated to the relevant  $\Sigma$  WHO-TEQ upper bound values for individual samples. Additionally, measurement uncertainty on lower bound total  $\Sigma$  WHO-TEQ has also been reported. In keeping with the convention of reporting lower bound data where concentrations below the reporting limit are not included in the summation, the estimation of uncertainty for the lower bound data similarly excludes the uncertainty associated with concentrations below the reporting limit. In order to facilitate comparison with other reports, whole weight basis  $\Sigma$  WHO-TEQs and measurement uncertainty estimates are also reported.

3.6 This report represents the first study of such a comprehensive set of brominated contaminants in foods from the UK. PBDEs occurred in most types of food and were the most frequently identified contaminant, followed by PBDFs, PBBs and HBCD. PBDDs were rarely identified and this observation is consistent with the environmental occurrence of PBDD/Fs. In general, these contaminants were most frequently observed in fish and to a lesser extent in processed meats, eggs and offals. Of the emerging BFRs identified by EFSA, there are a few instances of low level BTBPE occurrence in some samples. Little is known about the local production and use of BTBPE

– it was intended as a replacement for the banned BFR – Octa-BDE. Occurrence in sediment and biota have been documented (39, 40) for North America, and more proximately, levels of around 0.11 ng/g have been detected in birds eggs from the Faroe Islands (41). HBB and DBDPE were not detected in any samples. This is consistent with reports on the relatively low usage of DBDPE in the UK and occurrence in sediments/sludges (42). In general, the concentrations of most of the analytes reported here, reflect the utilisation of the various BFRs and the occurrence of brominated contaminants in the environment.

3.7 From a food safety point of view, there are no maximum permitted limits specified for any of the contaminants reported here and this is perhaps a reflection on the lack of comprehensive toxicological information and occurrence data. However, some of the more studied compounds such as PBDEs and PBBs have recently been added to the Stockholm Convention list of substances of very high concern (46). As far as observations on the concentrations of the various contaminants are concerned, and given the limitations on TEQs expressed earlier, it is however useful to note that the values recorded for PBDD/Fs and non –ortho PBB TEQ were generally below maximum permitted levels for the analogous chlorinated dioxins and PCBs, specified in EU regulations (43).

3.8 The levels reported of the various contaminants that were measured in this work are consistent with literature observations (where available) made for food (17-24,44). The general lack of data on the brominated contaminants does not allow observations on the trend in occurrence for these compounds. However, the data reported here represent a useful baseline from which data from future studies can be gauged. The continued use of BFRs and the resulting potential of PBDD/F formation from the disposal of these materials make it prudent to continue surveillance on the occurrence of these contaminants.

Table 1: Description of Samples

CSL Sample No.	Description	Fat %
15311	Mushy peas	0.6
15312	Cauliflower - Class II	0.4
15313	New Zealand sliced lambs liver	7.1
15314	Rainbow trout	6.9
15315	Organic boned Scottish salmon fillets	13.8
15316	English lamb hearts	8.1
15317	Best braising steak	3.3
15320	Boneless leg of pork	16.5
15321	Large eggs	8.8
15322	8 Lincolnshire sausages	15.3
15323	Vintage extra mature cheddar	35.2
15324	Wholemeal bread	2.8
15326	Rooster potatoes	0.2
15327	Carrots - Class 1 (20 - 50mm)	0.5
15328	Pure corn oil	100
15329	Sweetcorn	1.1
15344	Superfast Oats	9.1
15345	Organic extra jam handmade strawberry preserve	0.3
15346	Jersey potatoes in water	0.2
15347	Olive oil - medium	100
15348	Red onions - Class 1 (40/60mm)	0.3
15349	Somerset goat's cheese	28.9
15350	British white potatoes - Osprey	0.4
15351	Free range eggs - medium	10.1
15358	Swede half	0.1
15363	MSC wild Alaskan salmon fillets	2.9
15364	Crispy oven fries	5.4
15366	12 organic large free range eggs	9.0
15368	British parsnips	0.2
15369	Whole mackerel	12.2
15371	British classic tomatoes - Class 1	0.2
15373	6 Newmarket sausages	14.0
15374	Organic milk	3.2
15375	Cooked prawns - shell-on	2.2
15376	Ox kidney	8.7
15377	Dressed Whitby crab	6.2
15378	Boneless shoulder of lamb	15.3
15379	Turkey breast	6.2
15387	Leeks	0.1
15389	6 free range duck eggs	15.0
15390	Welsh medium Cheddar	34.7
15391	Welsh whole rainbow trout	5.5
15395	Ox liver	4.5
15397	Whole mackerel	10.0
15398	Wild Alaskan salmon fillet	3.4
15400	4 Scotch beef quarterpounders economy burgers	20.1

Table 1(cont'd): Description of Samples

CSL Sample No.	Description	Fat %
15401	Cheese spread	15.3
15403	Whole lemon sole	1.2
15404	Cod fillet	0.6
15405	Cheese & onion flavour potato crisps	32.8
15419	Blackcurrant coulis	0.7
15420	Free range organic eggs - medium	10.3
15421	Boneless British turkey breast joint	1.7
15422	British pork boneless leg roast	11.0
15424	4 haddock fillets	1.2
15425	Cornish brie	27.3
15426	Whole herring	17.6
15427	Plaice fillets	1.3
15429	Lambs liver	6.8
15430	Local venison fillet	2.5
15442	Black pudding	30.4
15443	Rump steak for braising	3.6
15444	Rolled shoulder of lamb	18.2
15445	Venison haugh joints	2.8
15450	Whole herring	24.1
15451	Cod fillet	0.7
15452	Farmed salmon fillet - (Freedom Food RSPCA monitored)	11.7
15487	Free range duck eggs	16.2
15488	Mini Pringles savoury snack	30.7
15493	Somerset brie	24.1
15498	Dover sole	1.2
15499	Plaice fillets	2.6
15500	Venison liver	3.4
15501	Lambs kidney	3.3
15503	Pure sunflower oil	100
15508	Smoked eel	39.1
15509	Medium half fat cheese food slices	10.4
15510	Duddleswell sheeps milk cheese	35.0
15511	Wild Atlantic salmon	9.0
15512	Whole Cornish sardines	15.1
15513	Pasteurised ewes milk	6.5
15516	Whole Cornish sardines - frozen	5.5
15526	Lambs kidney	3.7
15527	Pork liver	3.7
15528	Fresh chicken legs - boneless	15.2
15529	Chicken livers	4.5
15530	British pork sliced liver	3.8
15534	Chicken liver	5.3
15554	Mirror carp	4.9
15555	Whitebait	9.1

Table 1(cont'd): Description of Samples

CSL Sample No.	Description	Fat %
15557	Ox liver	3.3
15558	Duck liver pâté with wine	25.5
15564	Wild Atlantic salmon	7.8
15565	Whitebait	2.1
15566	Sprats	21.6
15567	English sprats	23.2
15569	Spinach - Class 1	0.4
15574	6 free range eggs - large	8.9
15579	Pigs kidney	3.1
15580	Boneless chicken thighs	17.8
15654	Eels	30.7

**Phase 2**

16143	Traditional lamb sliced liver	8.1
16145	Premium pork sausages	23.9
16150	Jellied eels	10.6
16151	Smoked eel	35.7
16159	Lochmuir Scottish salmon portions	16.5
16165	Wild venison liver	6.1
16166	Whole Cornish mackerel	24.8
16169	2 prime boneless salmon fillets	15.5
16170	8 Cumberland pork sausages	12.1
16172	Farmed red deer liver	5.9
16173	Lambs liver	6.4
16184	Whole mackerel (gutted by fishmonger)	2.1
16186	Herring (filleted by fishmonger)	19.4
